Homework 2

Wendi Chen

1 Q2: Time Complexity

In order to implement Lagrange Interpolation, we need to calculate the values of $l_k(x)(k \text{ from } 0 \text{ to } n)$ first and then use another loop to add them up to get the value at x. Because these two loops are nested, the time complexity is $O(n^2)$.

```
double ans = 0;
for(int i = 0; i < n; i + +){
    double s = Y[i];
    for(int j = 0; j < n; j + +){
        if(j!=i)
            s *=(x-X[j])/(X[i]-X[j]);
    }
    ans += s;
}
return ans;</pre>
```

For Newton Interpolation, there're mainly two steps. First, we need to use the difference method to calculate the coefficients. In my implemention, I allocate a $n \times n$ matrix to store intermediate values and execute a two-layer loop for calculation. This part accounts for a $O(n^2)$ time complexity.

```
\begin{array}{lll} \textbf{for}\,(\,\textbf{int} & i = 1; i \!<\! n; i \!+\! +\! ) \{ & \\ & \textbf{for}\,(\,\textbf{int} \ j = i; j \!<\! n; j \!+\! +\! ) \{ & \\ & table\,[\,i\,]\,[\,j\,] \!=\! table\,[\,i - 1][\,j\,] \!-\! table\,[\,i - 1][\,j - 1]; \\ & \} & \\ \} & \end{array}
```

Next, according to the definition of *Newton Interpolation*, calculate the t first and then bring in the coefficients, which also costs a $O(n^2)$ time complexity.

```
double t = (x-X[0])/h;
double ans = Y[0];
for(int i = 1; i < n; i++){
    double ans_k=table[i][i];
    for(int j = 1; j <= i; j++){
        ans_k/=1.0*j;
        ans_k*=1.0*(t-j+1);
    }
    ans+=ans_k;
}
return ans;</pre>
```

So, the overall time complexity of Newton Interpolation is also $O(n^2)$.

2 Q3: Drawing and Analysis

Since the interpolation range is not very large, and the existing points are evenly distributed, we can just divide the interval into 10,000 points and apply the above algorithms to each point. Then, use **Python** to visualize.

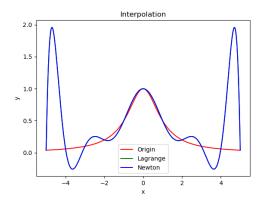

Figure 1: original function and interpolating polynomials from -5 to 5

As the Figure 1 shows, no matter we use Lagrange Interpolation or Newton Interpolation, we will get the **same** interpolating polynomials. This is predictable. It can be proved mathematically that the polynomials obtained by Lagrange interpolation and Newton interpolation are the same after simplification.

Also, the original curve and the interpolation curves intersect at the sampled points, which is permitted by the base functions we use in these two methods. However, the interpolation polynomial curves is more undulating than the original curve since we use polynomials to approximate. Specifically, in this case, as x is farther away from the central value (0), the function fluctuates more and the error is greater. Definitely, when x deviates from the range of the sampled points, a larger error will be caused (Figure 2).
